

Are all optical splitter ports the same

Overview

Optical splitters own different port configurations, generally represented as $M \times N$, indicating that this optical splitter has M input terminal (s) and N output terminals. A fiber broadband provider typically determines and overall split ratio for the network, such as 1x32 or 1x64, and uses combinations of splitters to meet that ratio with each PON port. 1x32 splits were common in North America for G-PON architectures. As XGS-PON continues to be adopted, some service. Optical splitters are the key passive component that enables “sharing” of OLT resources: Cost Efficiency: A single OLT port can serve 8-64 ONTs via a splitter, reducing the number of OLTs, fibers, and deployment labor needed. The optical splitter plays a critical role in applications such as passive optical networks (PONs), telecommunications networks, fiber-to-the-home (FTTH) installations, and more.
