

# Dense Wavelength Division Multiplexer Mux

## Overview

Dense wavelength-division multiplexing (DWDM) refers originally to optical signals multiplexed within the 1550 nm band so as to leverage the capabilities (and cost) of EDFAs, which are effective for wavelengths between approximately 1525–1565 nm (C band), or 1570–1610 nm (L band). This tutorial addresses the importance of scalable DWDM systems in enabling service providers to accommodate consumer demand. Dense Wavelength Division Multiplexing or DWDM is the method which allows multiple wavelengths to be brought to a single-mode fiber, consequently growing the potential of that particular transmission route by using a factor which is equal to the total number of wavelengths that one has added during. Corning's R&D scientists are constantly searching for new ways to improve wavelength division multiplexing (WDM) technology. This allows multiple channels of data to be transmitted simultaneously.
