

Does fiber optic communication suffer from crosstalk issues

Overview

The main challenge in optical networks involves crosstalk which constitutes unwanted signal interference that reduces transmission quality and restricts system capabilities. This is especially problematic in systems where multiple fibers are bundled together, such as fiber-optic. However, the close proximity of the cores can lead to data interference due to crosstalk between them. A novel approach is proposed to suppress crosstalk in MCFs. Far End Crosstalk is defined as the ratio of optical power from output port-1 to output port-2, assuming. Multi-core fiber (MCF) is a practical approach to realize space division multiplexing for high-capacity transmission in optical communication system. We show that the cross-talk not only depends on the numerical aperture and relative distance between the cores but also, crucially, on the size of the cores.
