

How to distinguish beam splitters

Overview

Beam splitters are classified by construction (plate, cube, pellicle, polka dot) and by function (standard, non-polarizing, polarizing, dichroic). Construction determines ghosting, damage threshold, and form factor. Function determines how polarization and wavelength are. Beamsplitters are optical components used to split incident light at a designated ratio into two separate beams. It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. a laser beam) into two (or sometimes more) beams, which may or may not have the same optical power (radiant flux). Good fit for large beam size applications at a reasonable price. This precise ability to direct light paths makes beam splitters essential in various applications, including imaging systems, laser. This Beamsplitters Selection Guide outlines the core types of beamsplitters, explains how they work, and provides practical advice for choosing the best one for your application.

In its most common form, a cube, a beam splitter is made from two triangular glass prisms which are glued together at their base using polyester, epoxy, or urethane-based adhesives. (Before these synthetic resins, natural ones were used, e.g. Canada balsam.) The thickness of the resin layer is adjusted such that (for a certain wavelength) half of the light incident through one "port" (i.e., face of the cube) is reflected and th
