

Raman Amplifier Classification

Overview

This Recommendation describes the classification, the type code and the reference models of various Raman amplifiers. It also outlines the general characteristics of Raman amplifiers, and defines the performance and testing parameters for them. It is often used in a fiber that carries a signal for a long distance (such as in an undersea cable). The basic principles for SRS are as follows: If weak signal light and strong pump light are transmitted along a. There are a number of applications where Single Frequency (SF) narrowband seed sources need to be amplified while maintaining spectral purity and with a minimum amount of added noise. Laser cooling of atoms often requires high power sources with very specific frequencies matching atomic transitions. Raman amplifiers (RAs) are fiber-optic amplifiers that use the transmission fiber itself as the gain medium via stimulated Raman scattering (SRS).

Raman amplification

Raman amplification /'rɑ:mən/ is a way of increasing the signal strength in an optical fiber. It is often used in a fiber that carries a signal for a long distance (such as in an undersea cable). Technically, it works by stimulating Raman scattering, in which a lower frequency "signal" photon induces inelastic scattering of a higher-frequency "pump" photon in an optical medium in the nonlinear regime. As a result, another "signal" photon is produced, with the surplus energy resonantly passed to the vibrational states of the
