

# The optical splitter output is connected to the optical transceiver

## Overview

The optical transceiver module (like an SFP, SFP+, or XFP module) in the OLT is the laser source that generates the initial light signal. This high-power signal is transmitted down the single fiber. Conversely, it can also combine multiple signals into one. Its primary role is in Passive Optical Networks (PON), which are the foundation of. The optical splitter can be centralized - only one optical splitter on the OLT PON port which means every user had their own fiber direct to the head end. The centralized. The configuration below has individual splitters at a central location, but addresses that are typically not reconfigurable by jumpers, so this configuration is a “distributed” split. In this scenario, the splitter is most often. A fiber-optic splitter, also known as a beam splitter, is based on a quartz substrate of an integrated waveguide optical power distribution device, similar to a coaxial cable transmission system.
