

What are the differences between optical splitters and switches

Overview

Optical switches enable dynamic signal routing with active control mechanisms, while splitters provide static signal distribution with inherent power division. The fundamental principle of optical switching involves directing optical signals through network paths without converting them to electrical signals, thereby maintaining signal integrity and reducing latency. This capability forms the foundation of point to multipoint network design, which is widely used in FTTH and campus fiber deployments. The internal. A “splitter” is a power splitter. A splitter is not a filter like a wavelength division multiplexer (WDM). Rarely, there can be two inputs to provide potential redundancy of route. Optical splitter. Understanding the distinctions between a network switch and a splitter can help you choose the right solution for your specific needs, whether you're setting up a simple home network or managing a large enterprise system.
