

What do silicon photonics and silicon photonics modules mean

Overview

Silicon photonics is the study and application of photonic systems which use silicon as an optical medium. The silicon is usually patterned with sub-micrometre precision, into microphotonic components. These operate in the infrared, most commonly at the 1. Unlike traditional chips that rely on electrical signals for data transmission, silicon photonics uses photons as the medium, transmitting data through optical waveguides. Silicon photonics is a technology for fabricating optical and electronic integrated circuit on silicon microchip. Where traditional computer chips push electrons through copper wires, silicon photonic chips guide photons (particles of light) through tiny channels called. Silicon photonics (SiPh) is an advanced technology that merges silicon-based semiconductor manufacturing with photonic components for data transmission, processing, and sensing. It enables optical communication on a silicon platform, bringing together the speed of light with the scalability of CMOS. A primary driver for the development of silicon photonics—and its emergence as a potential high-growth market—is the demand from optical communications. Extending Moore's Law is becoming increasingly difficult; post-nanometer breakthroughs face formidable obstacles, including skyrocketing.
